

## Lecture 11 Strings processing and functions

#### **Objectives**

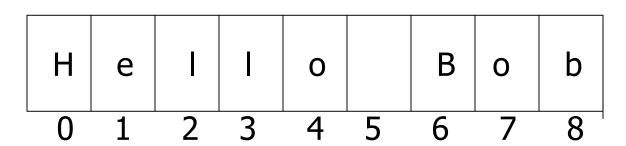

- Revision of string data type
- To get familiar with processing of strings
- To get familiar with various operations that can be performed on strings through built-in functions
- Take examples related to string processing

#### Revision: String Data Type

A string is a sequence of characters enclosed within quotation marks (") or apostrophes (')

```
>>> str1="Hello"
>>> str2='spam'
>>> print(str1, str2)
Hello spam
>>> type(str1)
<class 'str'>
>>> type(str2)
<class 'str'>
```

#### Revision: String indexing

In a string of n characters, the last character is at position n-1 since we start counting with 0.

```
>>> greet[1]
'e'
>>> greet[6]
'B'
>>> greet[-1]
'b'
>>> greet[-3]
'B'
```

#### Revision: String slicing / substring

```
        H
        e
        I
        I
        o
        B
        o
        b

        0
        1
        2
        3
        4
        5
        6
        7
        8
```

```
>>> greet[0:3]
'Hel'
>>> greet[5:9]
' Bob'
>>> greet[:5]
'Hello'
>>> greet[5:]
' Bob'
>>> greet[:] This is same as greet
'Hello Bob'
```

### Revision: String operations

Operator	Meaning
+	Concatenation
*	Repetition
<string>[]</string>	Indexing
<string>[:]</string>	Slicing
len( <string>)</string>	Length
for <var> in <string>:</string></var>	Iteration through characters

L11 Strings Processing - 6

#### Simple String Processing

- Abbreviations of species names.
  - In a particular bioinformatics database, names of species are abbreviated to the first 3 letters of the first part (genus) and first 2 letters of the second part (species)
  - For example
    - Canis familiaris (dog) ⇒ CANFA
    - Pan troglodytes (chimp) ⇒ PANTR

#### Simple String Processing

```
# get genus and species names
genus = input("Please enter the genus: ")
species = input("Please enter the species: ")

SPECIES_CODE = genus[:3] + species[:2]
# Convert to upper case
SPECIES_CODE = SPECIES_CODE.upper()
```

- We'll be looking at string functions, including upper(), later
- This form of functions are called methods. Notice variable name followed by dot followed by function call.

#### String Representation

- Inside the computer, strings are represented as sequences of 1's and 0's, just like numbers.
- A string is stored as a sequence of binary numbers, one number per character.
- The mapping of characters to binary codes is arbitrary
  - as long as everyone uses the same mapping.

#### String Representation

- In the early days of computers, each manufacturer used their own encoding of numbers for characters.
- ASCII system (American Standard Code for Information Interchange) uses 127 characters using 8-bit (1 byte) codes
- Python also supports Unicode which maps 100,000+ characters using variable number of bytes
- http://www.asciitable.com/

#### String Representation

- The ord function returns the numeric (ordinal) code of a single character.
- The chr function converts a numeric code to the corresponding character.

- Using ord and chr we can convert a string into and out of numeric form.
- The encoding algorithm is simple:
   get the message to encode
   for each character in the message:
   print the letter number of the character
- A for loop iterates over a sequence of objects, so the for loop over a string looks like:

  for <variable> in <string>

```
# text2numbers.py
#
      A program to convert a textual message into a sequence of
#
          numbers, utlilizing the underlying Unicode encoding.
def main():
    print("This program converts a textual message into a sequence")
    print ("of numbers representing the Unicode encoding of the message.\n")
    # Get the message to encode
    message = input ("Please enter the message to encode: ")
    print("\nHere are the Unicode codes:")
    # Loop through the message and print out the Unicode values
    for ch in message:
        print (ord (ch), end=",")—
                                               Replace new line by comma
    print() # Go to new line at the end of code sequence
```

# Shell >>> %Run encoder.py This program converts a textual message into a sequence of numbers representing the Unicode encoding of the message. Please enter the message to encode: fred Here are the Unicode codes: 102,114,101,100, >>>>

```
# A program to convert a textual message into a sequence of
# numbers, utilizing the underlying Unicode encoding.
Improved
def main():
    print("This program converts a textual message into a sequence")
    print ("of numbers representing the Unicode encoding of the message.\n")
    message = input("Please enter the message to encode: ")
    print("\nHere are the Unicode codes:")
    for ch in message[:-1]:
        print(ord(ch), end=",")
    print (ord (message [-1]))
```

- We now have a program to convert messages into a type of "code", but it would be nice to have a program that could decode the message!
- The outline for a decoder:

```
get the sequence of numbers to decode
message = ""
for each number in the input:
    convert the number to the appropriate character
    add the character to the end of the message
print the message
```

- The variable message is an accumulator variable, initially set to the empty string, the string with no characters ("" or '').
- Each time through the loop, a number from the input is converted to the appropriate character and appended to the end of the accumulator.
- How do we get the sequence of numbers to decode?
- Read the input as a single string, then split it apart into substrings, each of which represents one number.

• The new algorithm:

```
get the sequence of numbers as a string, inString
split inString into a sequence of small strings (of digits)
message = "" # Empty string
for each of the smaller strings:
    change the digits into the number they represent
    append the ASCII character for that number to message
print message
```

 $string \rightarrow list\ of\ digit\ strings \rightarrow list\ of\ numbers \rightarrow string$ 

```
"102,114" \rightarrow ["102","114"] \rightarrow [102,114] \rightarrow "fr"
```

- Strings have useful methods associated with them
- One of these methods is split. This will split a string into substrings based on a separator, e.g space.

```
>>> "Hello string methods!".split() This is a list.

['Hello', 'string', 'methods!'] — More about
them in the
next lecture
```

```
>>> a = "Hello string methods!"
>>> a.split()
```

• Split can use other separator characters other than space, by supplying the character as a parameter.

```
>>> "32,24,25,57".split(",")
['32', '24', '25', '57']
```

```
# numbers2text.pv
      A program to convert a sequence of Unicode numbers into
#
          a string of text.
def main():
    print ("This program converts a sequence of Unicode numbers into")
    print ("the string of text that it represents.\n")
    # Get the message to encode
    inString = input("Please enter the Unicode-encoded message: ")
    # Loop through each substring and build Unicode message
    message = ""
    for numStr in inString.split(","):
        codeNum = int(numStr) # convert the (sub)string to a number
        # append character to message
        message = message + chr(codeNum)
    print("\nThe decoded message is:", message)
```

- The split function produces a sequence of strings.
- Each time through the loop, the next substring is:
  - Assigned to the variable numStr
  - Converted to the appropriate Unicode character
  - Appended to the end of message.

#### Shell >>> %Run encoder.py This program converts a textual message into a sequence of numbers representing the Unicode encoding of the message. Please enter the message to encode: fred Here are the Unicode codes: 102,114,101,100, >>> %Run decoder.py This program converts a sequence of Unicode numbers into the string of text that it represents. Please enter the Unicode-encoded message: 102,114,101,100 The decoded message is: fred >>>

#### From Encoding to Encryption

- The process of encoding information for the purpose of keeping it secret or transmitting it privately is called *encryption*.
- *Cryptography* is the study of encryption methods.
- Encryption is used when transmitting credit card and other personal information through an insecure medium e.g. Internet.
- The Unicode mapping between character and number is an industry standard, so it's not "secret".

#### **Encryption: Substitution Cipher**

- In a simplistic way, if we replace the Unicode with some other code (that is only known to the sender and receiver) we will achieve encryption.
- This is called *substitution cipher*, where each character of the original message, known as the *plaintext*, is replaced by a corresponding symbol in the *cipher alphabet*.
- The resulting code is known as the *ciphertext*.
- This type of code is relatively easy to break.
- Each letter is always encoded with the same symbol, so using statistical analysis on the frequency of the letters and trial and error, the original message can be determined.

- There are a number of other string methods. Try them all! <a href="https://docs.python.org/3/library/stdtypes.html#string-methods">https://docs.python.org/3/library/stdtypes.html#string-methods</a>
  - str() Return a string representation
  - s.capitalize()  $Copy\ of\ s$  with only the first character capitalized
  - s.title() Copy of s; first character of each word capitalized
  - s.center(width) Center s in a field of given width

- s.count (sub) Count the number of occurrences of sub in s
- s. find (sub) Find the first position where sub occurs in s
- s.join(list) Concatenate list of strings into one large string using s as separator.
- s.ljust(width) Like center, but s is leftjustified
- s.rjust (width) Like ljust, but s is right-justified

- s.lower() Copy of s in all lowercase letters
- s.lstrip() Copy of s with leading whitespace removed
- -s.replace (oldsub, newsub) Replace occurrences of oldsub in s with newsub
- -s.rfind(sub) Like find, but returns the rightmost position

- s.rstrip() Copy of s with trailing whitespace removed
- s.split() Splits into a list of substrings
- s.upper() Copy of s; all characters converted to uppercase

#### Summary

- We learned how strings are represented in a computer.
- We learned about functions which can be used with strings.
- We took examples where various operations can be performed on strings.
- We learned fundamental concept of Cryptography.
